Integrated release validation

The completed f/p1 spectrum was reused. No TOV or Cowling eigenfrequency integrations were launched while preparing this integrated release.

Validation gates: - EOS intake: first-law knot identity, positivity, strict ordering, matching metadata and source hashes. - Adapter: positive monotone q, exact integral of n_B dmu_B, Euler energy reconstruction, causal sound speed, cubic-Hermite polynomial reproduction, per-table hashes. - Existing mode results: 234 unique rows, 78 per core family, VALID state, native-cell PASS, positive frequencies and expected (0,0)/(1,1) W/V node identities. - Software: pipeline unit tests, Python compileall, upstream generator regression suite and CLI smoke tests. - Documents: updated REVTeX source, BibTeX and paragraph review, PDF metadata and text extraction. - Release: SHA-256 manifest and ZIP integrity.

Known physical limitations remain those of the declared Cowling model: no metric perturbation, no gravitational-wave damping, no frozen-composition response, no sharp density interface and no zero-pressure surface extrapolation. The three-EOS tolerance study is representative convergence evidence, not a global error bound.

The q-linear table is a declared numerical thermodynamic realization, not a claim that the source generator EOS was thermodynamically inconsistent. Source tables remain intact.
